

EquityCurve

Pyth-anchored tokenized-stock launches on Meteora's Dynamic Bonding Curve.

Best Use of Meteora DBC · CWF side-track · \$20K USDC · Live on mainnet

THE THESIS

Tokenized equities launch at the wrong price and nobody trusts the pool. EquityCurve makes the **Dynamic Bonding Curve** the launch mechanism for synthetic stocks by pinning the curve's start price to **oracle fair value** — so the first swap prints the token exactly where Pyth says the asset trades, then climbs to the migration price.

REAL DBC USAGE (LIVE, NOT A MOCK)

Fair-Value Monitor

Reads live DBC virtual pools straight from the `dbc1j3LWUppWqQ96dh6gJWwBifmcGfLSB5D4DuSmaqN` program; derives spot via on-chain sqrt price; converts to USD with the on-chain SOL/USD push feed; shows premium/discount vs Pyth + migration progress.

Curve Studio

Enter a ticker → live reference quote → supply/decimal/fee params → generate a full `DBC ConfigParameters` via `buildCurveWithCustomSqrtPrices` — start price pinned so the first swap prints the token at Pyth fair value.

HOW THE DBC IS ORIGINAL

- Uses `@meteora-ag/dynamic-bonding-curve-sdk` against **real mainnet pools** (ASTROCOW/USDC, scade/SOL) — no testnet, no mock states.
- Curve config tuned for equity-like assets: oracle-pinned start sqrt price, fees and migration parameters exposed for judgment.
- Price layer is Pyth-native: 46 on-chain push feeds decoded from raw account bytes (zero RPC key) + Hermes equity feed IDs + PreStocks REST fallback.

WHY WE WIN THIS TRACK

- Directly and only about the DBC: launches, monitors, and prices them — the track's exact ask.
- **Working mainnet reads** of the DBC program today; deployable curve config generation.
- Only ~5 submissions at check — first-mover visibility.
